

Management of Asymmetric keys

Problems to solve

**Ensure proper and correct use of
asymmetric key pairs**

Privacy of private keys

- To ensure authenticity
- To prevent the repudiation of digital signatures

Correct distribution of public keys

- To ensure confidentiality
- To ensure the correct validation of digital signatures

Problems to solve

Temporal evolution of entity <-> key pair mappings

To tackle catastrophic occurrences

- e.g. loss of private keys

To tackle normal exploitation requirements

- e.g. refresh of key pairs for reducing impersonation risks

↳ não pode estar homodecodado ...

when the physical
bounds in real
world change => Keys must
change
we need to change
private Keys ...

Alguém ficou
desempregado! //

Problems to solve

Ensure a proper generation of key pairs

Random generation of secret values

- So that they cannot be easily predicted

Increase efficiency without reducing security

- Make security mechanisms more useful
- Increase performance

Goals

Key pair generation

- When and how should they be generated

Handling of private keys

- How do I maintain them private ?

Distribution of public keys

- How are they correctly distributed worldwide

Lifetime of key pairs

- When will they expire ↗ when a bound in real world change !
- Until when should they be used
- How can I check the obsolescence of a key pair ↗ is not expired but it is obsolet

Generation of key pairs: Design principles

Good random generators for producing secrets

Result is indistinguishable from noise

- All values have equal probability
- No patterns resulting from the iteration number or previous values

Example: Bernoulli $\frac{1}{2}$ generator

- Memoryless generator

- $P(b=1) = P(b=0) = \frac{1}{2}$ ↗ + e
negligible

- Coin toss

Generation of key pairs: Design principles

Facilitate without compromising security 

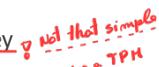

Efficient public keys

- Few 1 bits, typically $2k+1$ values (3, 17,  65537) 
- Accelerates operations with public keys
 - Cost is proportional to the number of 1 bits
- No security issues

Generation of key pairs: Design principles

Self-generation of private keys

Maximizes privacy as no other party will be able to use a given private key

- Only the owner has the key
- Even better: The owner doesn't have the key, but may use the key 

Principle can be relaxed when not involving signature generation

- Where there are not issues related with non-repudiation

Handling of private keys

Correctness

we need to verify the key!

The private key represents a subject

- e.g., a citizen, a service
- Its compromise must be minimized
- Physically secure backup copies can exist in some cases

The access path to the private key must be controlled

- Access protection with password or PIN
- Correctness of applications that use it

Handling of private keys

Confinement

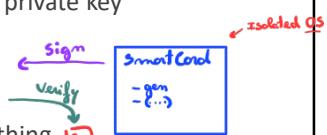

The signer should not know is Key

Protection of the private key inside a (reduced) security domain (ex. cryptographic token)

- The token generates key pairs
- The token exports the public key but never the private key
- The token internally encrypts/decrypts with the private key

Example: SmartCards

- We ask the SmartCard to cipher/decipher something
- The private key never leaves the SmartCard

Distribution of public keys

Distribution to all senders of confidential data

- Manual  send
 - Using a shared secret previously secret channel
 - Ad-hoc using digital certificates → Better
- ↙ ↘

Distribution to all receivers of digital signatures

- Manual
 - Ad-hoc using digital certificates
- ↙

Distribution of public keys

Problem: 
How to ensure the correctness of the public key?

Trustworthy dissemination of public keys

- Trust paths / graphs
- If A trusts K_x^+ , and B trusts A, then B trusts K_x^+
- Certification hierarchies / graphs
 - With the trust relations expressed between entities
 - Certification is unidirectional!

Not trust is gained with the lack of connection!

There are no built-in not trust!

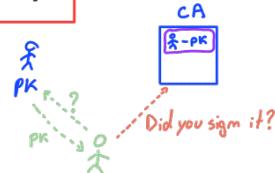

Public key (digital) certificates

Digital Document issued by a Certification Authority (CA)

Binds a public key to an entity

- Person, server or service

Are public documents

- Do not contain private information, only public one
- Can have additional binding information (URL, Name, email, etc.)

Are cryptographically secure

- Digitally signed by the issuer, cannot be changed

Public key (digital) certificates

Can be used to distribute public keys in a trustworthy way

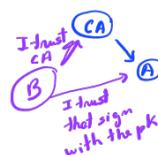

A certificate receiver can validate it in many ways

- With the CA's public key
- Can also validate the identification
- Validate the validity with a pre-defined public key
- Validate if the key is being properly used

• We trust the Certificate Authority !
⇒ we trust their keys !

A certificate receiver trusts the behavior of the CA

- Therefore, will trust the documents they sign
- When a CA associates a certificate to A
 - If the receiver trusts the CA
 - Then it will trust that the association of A is correct

Public key (digital) certificates

X.509v3 standard

- Mandatory fields
 - Version
 - Subject
 - Public key
 - Dates (issuing, deadline)
from: start date
to: end date
 - Issuer
 - Signature
 - terms de validade que valem da entidade certificadora!
 - etc.
- Extensions
 - Critical or non-critical

PKCS #6

- Extended-Certificate Syntax Standard
 - Format of the metadata

Not human readable!

① 1 - First step

Binary formats

- ASN.1 (Abstract Syntax Notation)
 - DER, CER, BER, etc.
- PKCS #7 *what are the algorithms used!*
 - Cryptographic Message Syntax Standard
- PKCS #12
 - Personal Information Exchange Syntax Standard

Standards for marshaling

Other formats

- PEM (Privacy Enhanced Mail)
- base64 encoding of X.509

② 2 - Sometimes we need human readable communication

Key pair usage

CertBot

The public certificate binds the key pair to a usage profile

- Private keys are seldom multi-purpose

↳ If you provide a website you need a CA to ensure the user's the security

Typical usage profiles

- Authentication / key distribution
 - Digital signature, Key encipherment, Data encipherment, Key agreement
- Document signing
 - Digital signature, Non-repudiation
- Certificate issuing (exclusively for CAs)
 - Certificate signing, CRL signing
- Timestamping (exclusively for TSAs)
 - When was that signature produced?

Public key certificates have an extension for this

- Key usage (critical) *determines the validation ...*

Dizer o tipo da chave pública, e assim os esse tipo! e.g.: DigitalSignatureKey, KeyEncipherment

!

Certification Authorities (CA)

Organizations that manage public key certificates

- Companies, not for profit organizations or governmental
- Have the task of validating the relation between key and identity
is this key from this website? //

Define policies and mechanisms for:

- Issuing certificates *padin*
- Revoking certificates *cancelar/revogar*
- Distributing certificates *distribuir*
- Issuing and distributing the corresponding private keys

Manage certificate revocation lists

- Lists of revoked certificates *if the certificate has expired*
- Programmatic interfaces to verify the current state of a certificate

Chain of Trust

Trusted Certification Authorities

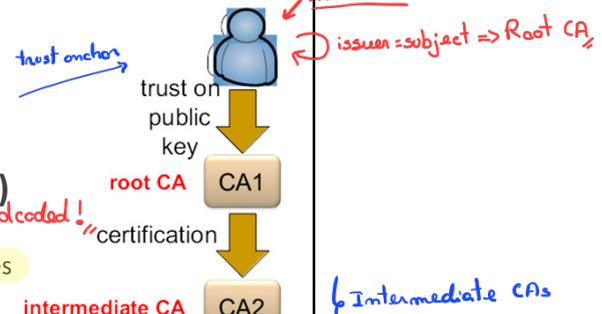

Intermediate CAs: CAs certified by other trusted CAs

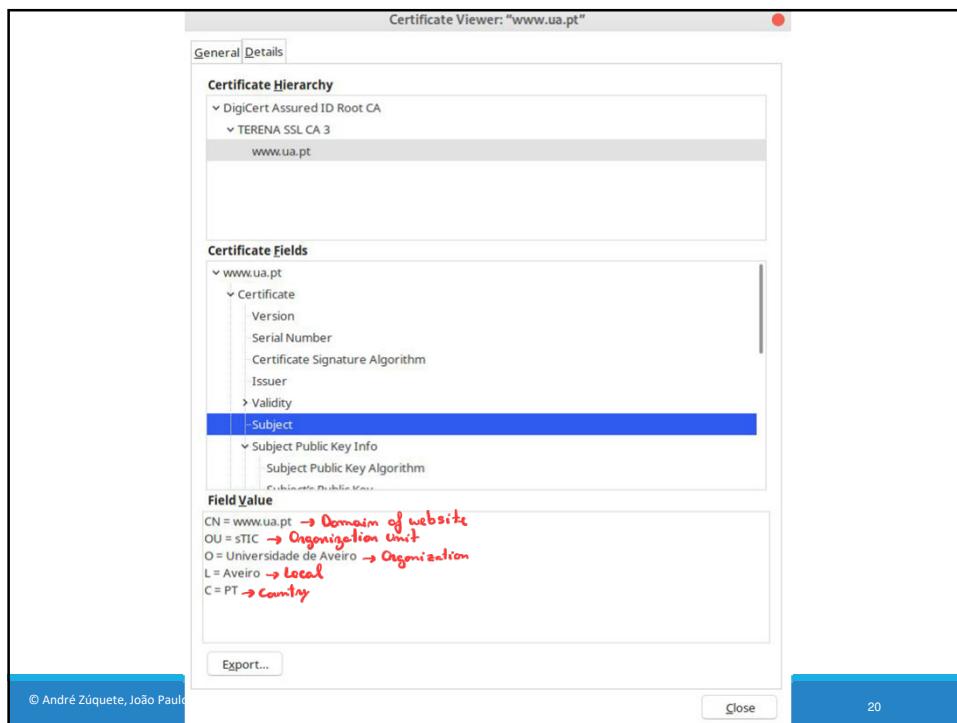

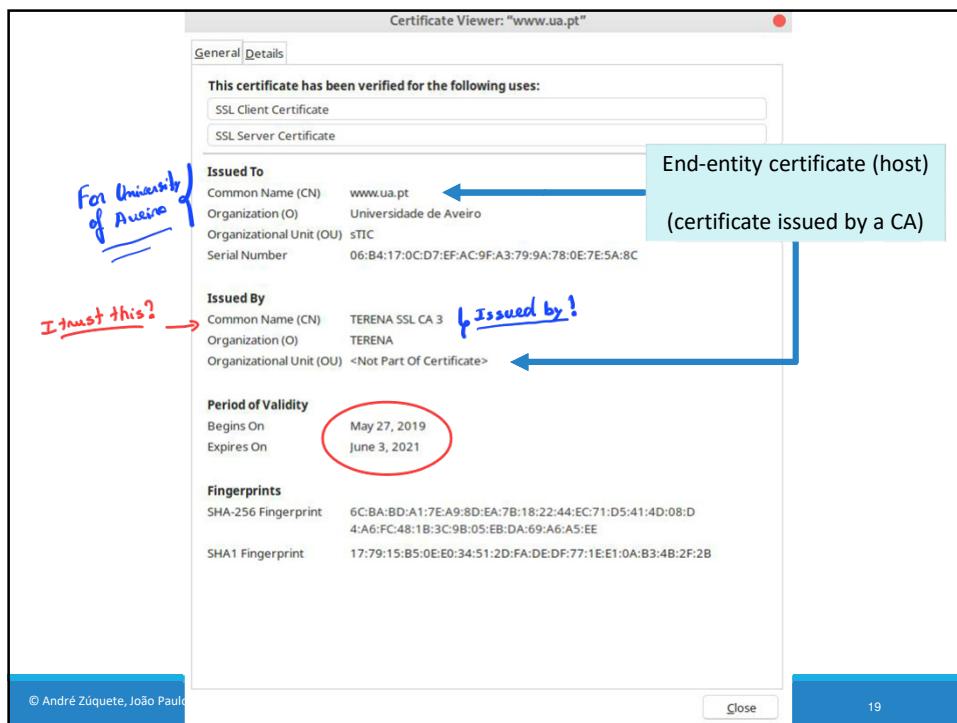

- Using a certificate
- Enable the creation of certification hierarchies

Trusted anchor (or certification root)

- One that has a trusted public key *normally hardcoded!*
- Usually implemented by self-certified certificates
 - Issuer = Subject
- Manual distribution
 - e.g., within browsers code (Firefox, Chrome, etc.), OS, distribution...

↳ Public Key is signed with her private Key! ↳ the root anchor certify herself

Now, I trust this...

Certificate Viewer: "TERENA SSL CA 3"

General **Details**

This certificate has been verified for the following uses:
SSL Certificate Authority

Issued To

- Common Name (CN): TERENA SSL CA 3
- Organization (O): TERENA
- Organizational Unit (OU): <Not Part Of Certificate>
- Serial Number: 08:70:BC:C5:AF:3F:DB:95:9A:91:CB:6A:EE:EF:E4:65

Issued By

- Common Name (CN): DigiCert Assured ID Root CA *Root CA*
- Organization (O): DigiCert Inc
- Organizational Unit (OU): www.digicert.com

Period of Validity

- Begins On: November 18, 2014
- Expires On: November 18, 2024

Fingerprints

- SHA-256 Fingerprint: BE:B8:EF:E9:B1:A7:3C:84:1B:37:5A:90:E5:FF:F8:04:88:48:E3:
A2:AF:66:F6:C4:DD:7B:93:8D:6F:E8:C5:D8
- SHA1 Fingerprint: 77:B9:9B:B2:BD:75:22:E1:7E:C0:99:EA:71:77:51:6F:27:78:7C:AD

Refreshing of asymmetric key pairs

Key pairs should have a limited lifetime

- Because private keys can be lost or discovered Revocation list
- To implement a regular update policy

Problem

- Certificates can be freely copied and distributed
- The universe of holders of certificates is unknown
 - Therefore, we cannot contact them to eliminate specific certificates

If the key was compromised in the valid period we cannot say that it was compromised //

Solutions

- Certificates with a validity period (not before, not after)
- Certificate revocation lists
 - To revoke certificates before expiring their validity

Solution

Certificate revocation lists (CRL)

Revocation Lists ...
↑
Revocation

Base or delta

- Complete / differences

Signed lists of certificates (identifiers) prematurely invalidated

- Must be regularly consulted by certificate holders
- OCSP protocol for single certificate validation
 - RFC 2560 → standard
- Can tell the revocation reason

incomplete, but valid
!!??!

RFC 3280

- unspecified (0)
- keyCompromise (1)
- CACompromise (2)
- affiliationChanged (3)
- superseded (4)
- cessationOfOperation (5)
- certificateHold (6)
- removeFromCRL (8)
- privilegeWithdrawn (9)
- AACompromise (10)

The CA must sign the Revocation List

Publication and distribution of CRLs

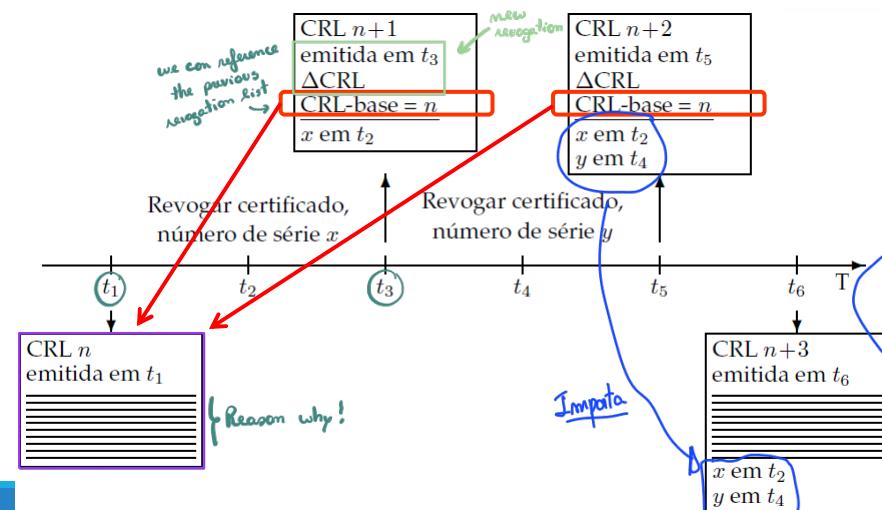

- Each CA keeps its CRL and allows public access to it

© André Zúquete, João Paulo Barraca

INFORMATION AND ORGANIZATIONAL SECURITY

31

CRL and Delta CRL

✗ Not used

OCSP - Online Certificate Status Protocol

Online Certificate Status Protocol

OCSP → one check per certificate!

HTTP-based protocol to assert certificate status

- Request includes the certificate serial number
- Response states if the certificate is revoked
 - Response is signed by the CA and has a validity
- One check per certificate

How to validate
without downloading
the full updated
CRL //

Response is
signed by the CA
and has a validity

Requires lower bandwidth to clients → we do not need to download the full CRL

- One check per certificate instead of a bulk download of the CRL

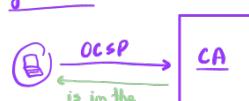

Involves higher bandwidth to CAs

- One check per certificate
- Privacy issues as the CA will know that a certificate is being used

OCSP stapling

- Including a recently signed timestamp in the server response to assert validity
- Reduces verification delay and load on CA
- Avoids privacy issues

Solution

Mes os CA agora sabem quando e quantos acedem a quele serviço ...

Distribution of public key certificates

Transparent (integrated with systems or applications)

- Directory systems
 - Large scale (ex. X.500 through LDAP)
 - Organizational (ex. Windows 2000 Active Directory (AD), Manually (UA IDP))
- On-line: within protocols using certificates for peer authentication
 - e.g. secure communication protocols (TLS, IPSec, etc.)
 - e.g. digital signatures within MIME mail messages or within documents

Explicit (voluntarily triggered by users)

- User request to a service for getting a required certificate
 - e.g. request sent by e-mail
 - e.g. access to a personal HTTP page

PKI (Public Key Infrastructure) (1/2)

Infrastructure for enabling a proper use of asymmetric keys and public key certificates

Creation of asymmetric key pairs for each enrolled entity new website => new key pair

- Enrolment policies
- Key pair generation policies

Creation and distribution of public key certificates

- Enrolment policies
- Definition of certificate attributes

PKI (Public Key Infrastructure) (2/2)

Definition and use of certification chains (or paths)

- Insertion in a certification hierarchy
- Certification of other CAs

Update, publication and consultation of CRLs

- Policies for revoking certificates
- CRL distribution services
- OCSP services

Use of data structures and protocols enabling inter-operation among components / services / people

Portuguese

PKI Example: Citizen Card

Enrollment

- In loco, personal enrolment
*we use in a store...
validated in the place*

Multiple key pairs per person

- One for authentication → *this is the citizen that we are expecting*
- One for signing data
- Both generated inside smartcard, not exportable → *is inside that chip*
- Both require a PIN to be used in each operation

Certificate usage (authorized)

- Authentication
 - SSL Client Certificate, Email (Netscape cert. type)
 - Signing, Key Agreement (key usage)
- Signature
 - Email (Netscape cert. type)
 - Non-repudiation (key usage)

↳ Append the signature, for file validation ...

Certification path

- Uses a well-known, widely distributed root certificate
 - GTE Cyber Trust Global Root
 - PT root CA below GTE
 - CC root CA below PT root CA
 - CC Authentication CA and CC signature CA below CC root CA

CRLs

- Signature certificate revoked by default
 - Revocation is removed if the CC owner explicitly requires the usage of CC digital signatures
- All certificates are revoked upon a owner request
 - Requires a revocation PIN
- CRL distribution points explicitly mentioned in each certificate

```

graph TD
    PT[PT Root CA] --> CC[CC Root CA]
    subgraph "Certification path"
        PT
        CC
        GOV["GOV"]
        GOV --- CC
    end
    
```

Certificate Pinning

If attacker has access to trusted Root, it can impersonate every entity

- Manipulate a trusted CA into issuing certificate (unlikely)
- Inject custom CA certificates in the victim's database (likely)

✓ Solution

Verdadeiramente, para os sites principais o browser já sabe os fingerprints

Not perfect

Certificate Pinning: add the fingerprint of the PubK to the source code

- Fingerprint is a hash (e.g. SHA256)
we use the fingerprint of the certificate

→ Man-in-the-middle Attack

Validation process:

- Certificate must be valid according to local rules
- Certificate must have a public key with the given fingerprint

Certification Transparency (RFC 6962)

Problems

- CAs can be compromised (e.g., DigiNotar)
 - By attackers
 - By governments, etc.
- Compromise is difficult to detect
 - Result in the change of assumptions associated to the behavior of the CA
 - Owner will selfdom know

Definition: a global system records all public certificates created

- Ensure that only a single certificate has the correct roots
- Stores the entire certification chain of each certificate
- Presents this information for auditing
 - Organizations or ad-hoc by the end users
